

Experimental page : ratios of curve fit deaths to curve fit confirmed cases (CFR)

Demonstration of SIR model where R_e is linearly reduced to 0.80 at the end of the sequence:

Reducing the R_e while keeping gamma constant is the same as reducing contact rate. Contact rate is reduced through isolation, lockdowns, and vaccinations. Seems to indicate timing of start of measures is a big factor. The orange data taken as without measures, but we know certain measures were taken. Hard to determine effect, without a basis of comparison.

False Positives Demonstration

Use 0.11% from US est. incidence above as estimated daily incidence
Prevalence estimated as avg. infected period of 2 weeks X incidence
99% accuracy of test
0.11% X 14 = 1.540%

	Positive	Negative	
test pos	1.525%	0.985%	2.51%
test neg	0.015%	97.475%	97.49%
	1.540%	98.460%	100.00%

False pos. is less than half of total positives.		
TRUE +	1.525%/2.51%	60.8%
FALSE +	0.985%/2.51%	39.2%
Total		100.00%

Counter-act this tendency by increasing test sensitivity. However this may increase false negatives, the recipients of which may be positive, think they're negative, and go spread it around some more.

<https://data.cdc.gov/NCHS/Excess-Deaths-Associated-with-COVID-19/xkxf-xrst/data>

USA Excess Deaths (from CDC data):

Annualized on 52 weeks			
	All Cause	All Cause, excl. CV19	CV19
3 yr average before 2020	859:100,000	859:100,000	-
2020	1014:100,000	904:100,000	-
Diff.	155:100,000	44:100,000	111:100,000

3 yr average
859:100,000

29% of All-Cause excess deaths are non-CV19

<https://data.cdc.gov/NCHS/Excess-Deaths-Associated-with-COVID-19/xkxf-xrst/data>

$K = 0.318$ $R_o :$ $R :$

$\gamma = 0.171$ $R_o = \exp(K/\gamma) = 6.42$ 84%

$\gamma = 0.286$ $R > 1 - 1/R_o = 3.04$ 67% \leq Herd immunity

R is recovered variable.

Here are some demonstrations of SIR model, using R_e , gamma, and beta
