Experimental page: ratios of curve fit deaths to curve fit confirmed cases (CFR)

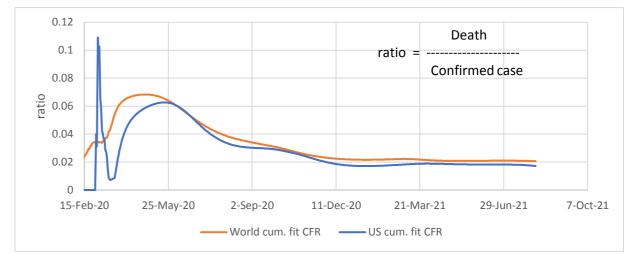

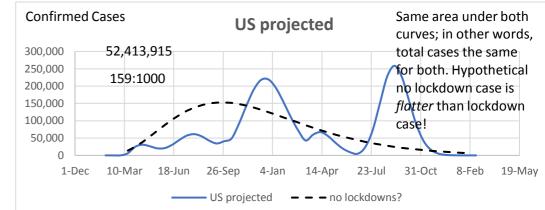

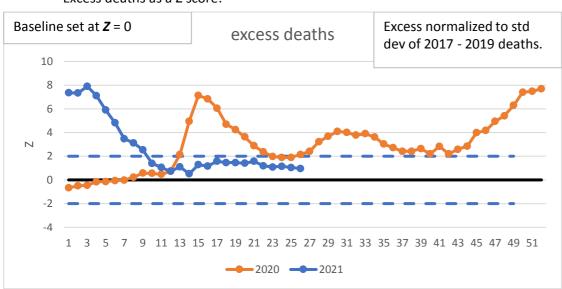

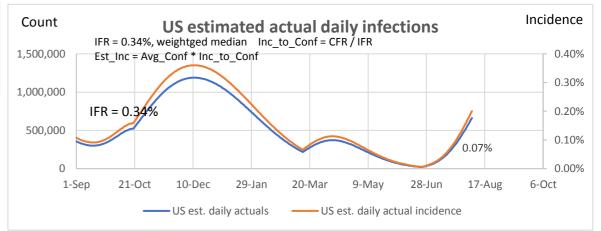

Excess deaths as a Z score:

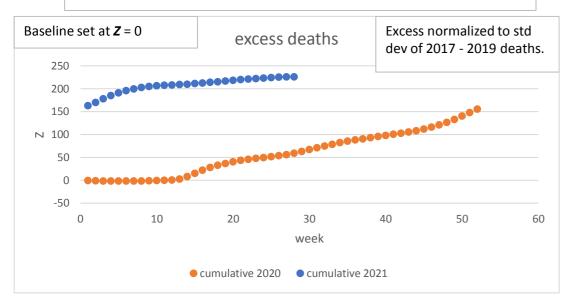

Above based on Z score of two year standard deviation from 2017-2019. What follows is cumulative plot of same.

False Positives Demonstration

Data in recent weeks are incomplete. Only 60% of death records are submitted to NCHS within 10 days of the date of death, and completeness varies by jurisdiction. Data are not weighted and counts are likely

Use 0.07% as estimated daily incidence *Prevalence* estimated as avg. infected period of 2 weeks X incidence

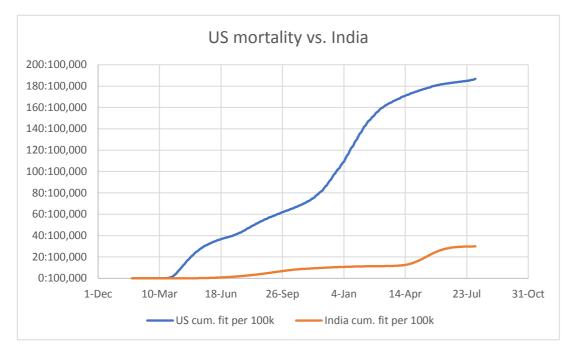

99%	accuracy o	f test		0.07% X 14 = 0.980%
	Positive	Negative		
test pos	0.970%	0.990%	1.96%	
test neg	0.010%	98.030%	<u>98.04%</u>	
	0.980%	99.020%	100.00%	

False pos. is more than half of total positives.

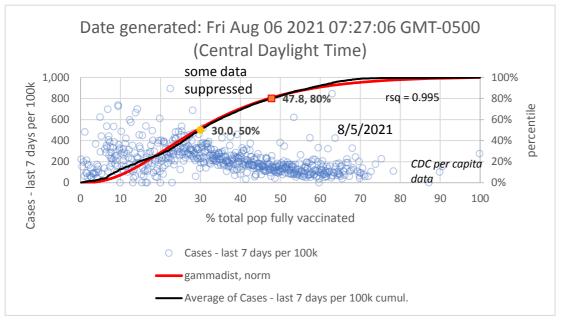

TRUE + 0.97%/1.96% 49.5% FALSE + 0.99%/1.96% 50.5% Total ------ 100.00%

Counter-act this tendency by increasing test sensitivity. However this may increase false negatives, the recipients of which may be positive, think they're negative, and go spread it around some more.

K = 0.318 R_o : R:

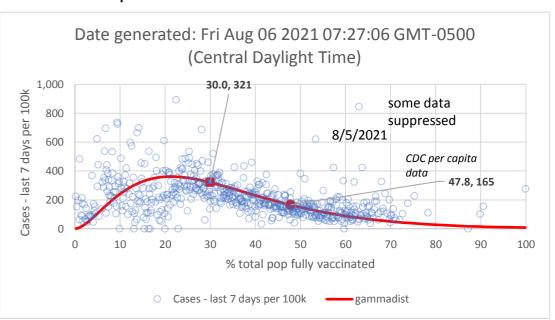

gamma = 0.171 $R_o = \exp(K/\text{gamma}) = 6.42$ 84%

gamma = 0.286 $R > 1 - 1/R_o = 3.04$ 67%

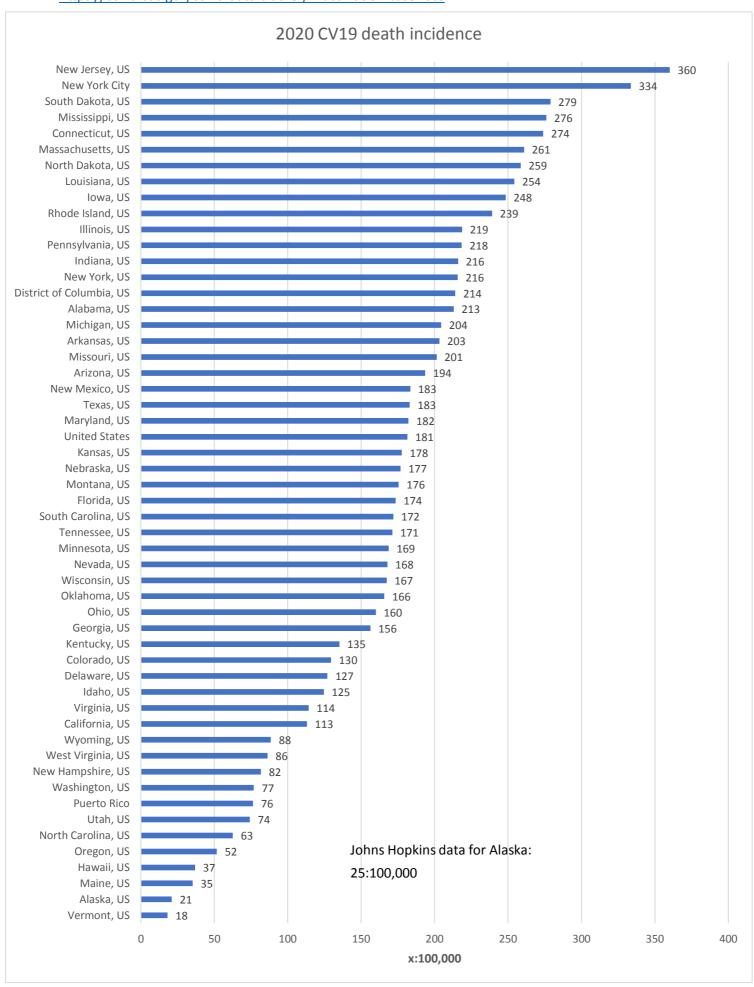

R is recovered variable.

Estimates of Cases per 100k

reporting jurisdictions is not a uniform distribution; some data suppressed, for example Texas curve fit constrained by 100% vaccinated at 100 percentile
